

Logic in Computer Software

Yukiyoshi Kameyama

Dept. of Computer Science, Univ. of Tsukuba

Week 5

Safety in Staged Programs

Dangerous (not safe) and ill-typed program:

```
<x + 10> ;;
let x = 5 in <x + 10> ;;
```

Safe and well-typed program:

```
<fun x -> x + 10> ;;
<let x = 5 in x + 10> ;;
```

But there are

- Safe and ill-typed programs.
- Dangerous (not safe) and well-typed programs. (Problem!).

Type-safe code generation as meta-programming.

- What is safety ?
- How is it guaranteed ?
- Why is it good ?
- Types as a means to guarantee safety.
- Safety, Reliability and Dependability.

Dangerous Program

Dangerous (not safe) and well-typed programs in the original MetaOCaml.

```
let x = ref 10;;    ==> reference (pointer) to 10
!x ;;             ==> 10
x := !x * 2 ;;    ==> ()
!x ;;             ==> 20
```

```
let x = ref <10> in
let _ = < fun y -> ~( x := <y> ; <()> ); 20> in
! x
==>
<y>
```

For an example in the latest MetaOCaml, see the paper [Shan 2010].

Safety here means **type safety**.

- Subject Reduction Property (Preservation Property)
- Progress Property

Subject Reduction: if $\Gamma \vdash^n e : \tau$ is derivable, and $e \rightsquigarrow^* e'$, then $\Gamma \vdash^n e' : \tau$ is derivable.

Progress: if $\vdash^0 e : \tau$ is derivable, and e is not a value, then $e \rightsquigarrow e'$ for some e' .

"Well-typed programs do not go wrong".

Static safety guarantee of no syntax error, no type error and no scope error (no free variables) in generated codes:

Approach	no syntax error	no type/scope error
Strings as codes	NG	NG
Lisp Quasiquote	OK	NG
C++ template	OK	NG
Template Haskell	OK	NG
Scala LMS	OK	NG
MetaOCaml	OK	OK

Note. Safety means "no compile errors for generated codes", and it does NOT imply the generated codes are correct.

What are implied by type safety in MSP ?

If $\Gamma \vdash e : \tau$ is derivable, then

- no type error in e ; compilation of e does not cause an error.
- no type error during the execution of e ; for instance, we will never add a string with a code.
- If the computation of e terminates and $\tau = \langle \sigma \rangle$, then its result is $\langle e' \rangle$. (code is generated.)
- and e' is well-typed. (generated code is well typed)

If e is `run` e' , then type safety guarantees the absence of type error during the execution of the generated code from e' .

"Well-typed code-generators as well as codes generated from them do not go wrong".

A generic yet efficient algorithm [Jacques Carette 2005 "Gaussian Elimination: a case study in efficient genericity with MetaOCaml", in SCP].

- Maple: a large **commercial** computer algebra system.
- Gaussian Elimination (GE) is an algorithm on square matrices.
- Maple contains **35** different implementations of GE with parameters such as:
 - Domain of matrix elements: $Z, Q, Z_i, Z[x], Q(x), Q(\alpha)$, and `float`, ... (20 different domains).
 - Fraction-free (or remainder-free) division or not.
 - Representation of matrices: array of arrays, one-dimensional array, hash table, and indexing is done in C-style or FORTRAN-style.
 - Length measure for pivoting.
 - Output choices.
 - Normalization and zero-equivalence.
- Parameter choices are not independent and more design choices: 35 different implementations, still share the same

Applications of Staging (GE-2)

Question: is it OK to maintain all 35 implementations ?

Probably no.

- algorithm change may affect all implementations.
- some implementation may not utilize optimization used in other implementations.
- we need abstraction (for reusability, maintainability, and reliability).

Applications of Staging (GE-4)

Solution: use staging.

- We write only one (generic) program in MetaOCaml, and maintain this code only.
- By staging, we generate 35 (and possibly more) different codes using specific parameters for each choice.
- The package (commercial product) contains these codes.
- The generic program is easy to read, but bad in efficiency.
- The generated codes are hard to read, but good in efficiency.

Moreover, in the MetaOCaml-style staging, the generator (program) looks like the generated codes.

Applications of Staging (GE-3)

Question: is it enough to represent all 35 implementations by one generic program ?

No, definitely.

- Maple is a **commercial** system, and efficiency is important.

```
let ge_high findpivot swap zerobelow a m n = ...
  if (domain = int) then ...
  else if ....
  if (fraction_free) then ...
  else ...
  let new_matrix = add_row (i, j, old_matrix) in ...
```

Many places to be improved:

- Conditionals and Case analysis are bad for efficiency.
- Function calls should be eliminated by inlining (if we know which function is called statically).

Applications of Staging (DSL interpreter-1)

Domain-specific language (DSL) is ubiquitous. (vs. General-purpose programming languages):

- database access
- parser generator (e.g., lex/yacc)
- wiki
- (according to wikipedia) DSL for life insurance policies, combat simulation, salary calculation, billing, ..

If we have enough resource (time, man-power etc.), we can develop a compiler for each DSL, but often it's not possible (and not necessary).

We usually write an interpreter of DSL.

Applications of Staging (DSL interpreter-2)

A typical DSL interpreter (written in OCaml):

```
let rec eval exp env =  
  match exp with  
  | Int i -> i  
  | Add e1 e2 -> (eval e1 env) + (eval e2 env)  
  | If e1 e2 e3 -> if (eval e1 env) then ...  
  ...
```

interpretive overhead: if we run the power function (or any recursive function), we interpret the same function many times. (power 1000 needs to be interpreted 1000 times, rather than once.)

Applications of Staging (High Performance Code)

Aktemur, Kameyama, Kiselyov, Shan [2013], "Shonan Challenge for Generative Programming":

- Based on our technique for generating efficient codes using MetaOCaml-like staging,
- we propose a set of **challenging** programs in high-performance computing (such as computer algebra, fast Fourier transform, hidden Markov model etc.),
- and ask Staging people to provide **good** solutions for them.

Applications of Staging (DSL interpreter-3)

Staging will help the situation. We can generate the code (in the general purpose language) for a program in DSL, then run it.

We only have to interpret each program once.

```
let rec eval exp env =  
  match exp with  
  | Int i -> <i>  
  | Add e1 e2 -> <~(eval e1 env) + ~(eval e2 env)>  
  | If e1 e2 e3 -> <if ~(eval e1 env) then ...>  
  ...
```

Walid Taha 2005, "A Gentle Introduction to Multi-Stage Programming" reported 5 - 20 times speed up of staged DSL interpreter.

Evaluation Criteria of Shonan Challenge

- efficiency
- reusability/maintainability
- safety (and possibly verifiability)
- ease of use
- and more

Still hot and active research area.

これまでの授業を参考にして、以下の各項目について、自分の考えを述べよ。

- 「プログラムによるコード生成」という考え方 (MetaOCaml 風でなくてよい) について、(1) 自分の研究や趣味に関連する分野で、どのように使われているか、あるいは使われていると良いか、(2) また、コード生成のためのどのような言語、ライブラリ、プログラミング環境があれば良いとおもつか、などを、自由に書きなさい。
- 「プログラム言語の型システムの役割」について、自分がこれまで作成したソフトウェア (あるいは作成中のシステム) において、どのように使われているか、役に立ったか立たなかったか、どういう風な型システムであれば嬉しいか、など、自由に書きなさい。
